**24 School Street, Wayland MA**

**Introduction**

The project site is located on the northerly side of East Plain Street at the intersection of East Plain Street and School Street. The locus is shown on Figure One: Locus Map, 24 School Street, Wayland MA.

The subject parcel (Assessors' Map 52, Lot 189) has an area of 37,865 square feet (0.87 acres). The property is improved with a two-story house, a one-story barn, a detached garage, and a patio. The lot consists of mostly gravel, landscaped and lawn areas with moderate topographic relief across the site. The site slopes from higher elevations near School Street to the southwest with a maximum elevation differential on site of approximately ten-feet. A wetland is located west of the property and a portion of the lot falls within the 100' buffer zone.

According to the NRCS Soil Survey, the southerly portion of the lot consists of Narragansett Silt Loam (415B) soil series and are classified within hydrologic soil group A. Narragansett soils are a well drained glacial till that exhibit moderately high to high infiltration rates when saturated. The northerly portion of the site consists of Hinckley loamy sand soil group (253C). Hinckley soils are a very well-drained soil with good hydraulic conductivity. Runoff curve numbers for Hydrologic Soil Group B were used for the analysis based on soil conditions observed during field testing and the inconsistencies between hydrologic soil group and soil descriptions in the soil survey.

An on-site soil evaluation program consisting of twelve deep test holes was conducted on July 21 and August 21, 2014. DTH-1, 2, 3, 6, 7, 9, and 10 were all conducted on the north side of the lot. Results revealed the A horizon consisting of fine sandy loam at a depth of roughly 12 inches, the B horizon consisting of fine sandy loam to a depth of roughly 24 inches, with C horizons consisting of sandy loam at 60 inches and 120 inches respectively.

DTH-4 and 5 were conducted on the south side of the lot. DTH-4 had the A horizon at 28 inches, with the first 20 inches being fill. The B horizon consisted of fine sandy loam and had a depth of 40 inches. The C horizons consisted of sandy loam and were found at 86 and 116 inches respectively. DTH-5's A horizon consisting of fine sandy loam was found at 16 inches. The B horizon consisting of fine sandy loam was found at 34 inches. The C horizons consisting of sandy loam were found at 84 and 117 inches respectively.

DTH-11 and 12 were conducted on the east side of the lot. DTH-11 has fill to a depth 18 inches, with the A horizon of fine sandy loam at 30 inches, the B horizon of fine sandy loam at 36 inches, and the C horizons of sandy loam at 58 and 128 inches respectively. DTH-12 has fill to a depth of 54 inches, bypassing the A and B horizons, the C horizons of sandy loam were found at 82 and 114 inches respectively.

No refusal was observed in any of the test pits. Redoximorphic features were found in 10 of the 12 test pits at depths of 5 to 7 feet. The groundwater elevations varied from 155-feet to 162-feet.

The site redevelopment program includes the construction of two new multifamily dwellings, paved parking areas, storm water management system and supporting utilities. See site plans for details regarding the proposed development.

The property presently contains 8,780 square feet of impervious area. Redevelopment of the property will increase the amount of impervious area by adding 11,283 square feet for a total of 20,063 square feet.

### **Drainage Approach**

There are presently no controls in place to manage stormwater runoff rates or volumes. Stormwater runoff drains to the west and south to abutting properties and into East Plain Street. The goal of the proposed stormwater management system is to reduce runoff rates and volumes for all design storms compared to the existing condition and to promote groundwater recharge using a subsurface infiltration system and a rain garden.

The proposed subsurface infiltration system will be located under the parking lot between the two structures. The system will consist of 84 precast concrete infiltration galleys surrounded by two feet of double washed, crushed stone. The infiltration system will collect runoff from Post-Development Basin 4, which consists of the parking area and a portion of the proposed roof structures. The proposed infiltration system is designed to completely contain and recharge runoff from storms up to the 10-year storm. The proposed rain garden will collect and store runoff from Post-Development Basin 3A which consists of the easterly portion of the roof of Building A and the surrounding lawn and landscaped areas. The storm water management system will significantly reduce runoff rates and volumes from the subject parcel for all storm events.

Overall reductions in runoff rates and volumes can be found in the Model Results section of this report and detailed hydrologic analysis and basin models can be found in Appendix A.

### **Hydrologic Analysis**

A hydrologic analysis of the project has been performed to establish pre-development conditions, assess post-development impacts and evaluate the effectiveness of the proposed drainage infiltration systems. The analysis employs an SCS TR-55 hydrologic computer model and analyzes design storms with return periods of 2, 10, 25 and 100-years. An SCS Type 3 24-hour rainfall distribution pattern is used for the theoretical design storm. Time of concentration values were determined by the LAG Method or manually entered at five minutes for watersheds having relatively small areas or hydraulic lengths to allow for the use of a three-minute time interval for all hydrograph computations. Precipitation rates of 3.20, 4.73, 5.95 and 8.45-inches were used for the 2, 10, 25 and 100-year storm events respectively. Runoff curve numbers for Hydrologic Soil Group B were used for the analysis based on soil conditions observed during field

testing and the inconsistencies between hydrologic soil group and soil descriptions in the soil survey.

### Existing Conditions

The existing conditions model analyzes the site as three drainage basins; Existing Conditions Basins One, Two, and Three.

Existing Conditions Basin 1 (E.C.B.-1) has an area of 15,276 square feet and flows in a southwesterly direction to Design Point A located at the west side of the property.

Existing Conditions Basin 2 (E.C.B.-2) has an area of 2,901 square feet and flows in a northeasterly direction to Design Point B located at the northeast side of the property.

Existing Conditions Basin 3 (E.C.B.-3) has an area of 19,688 square feet and flows in a southwesterly direction to Design Point C located at the southwest corner of the property.

The Existing Conditions Basins are shown on Figure Two, Existing Conditions Watershed Delineation Plan and information for all Existing Conditions Basins is listed on the plan and below.

### *Drain Infiltration Systems*

#### *Proposed Infiltration System 1*

Basic geometry: 32.0 feet wide by 52.0 feet long  
 System type: Shea Leaching Galleys; 360 gallons each  
 Use 84 Galleys; 4-feet long by 4.5-feet wide by 3.0-feet high  
 Surrounded by two feet of double washed, crushed stone  
 Infiltration rate: 1.02 inches per hour over 1,664 square foot bed

#### *Proposed Rain Garden*

Basic geometry: Irregular shaped basin  
 System type: Constructed basin approximately 1.5-feet deep  
 Total Storage approximately 742 cubic feet  
 Infiltration rate: 1.02 inches per hour over 450 square foot bed area

The proposed condition model analyzes the infiltration system using a reservoir-analysis method. Consistent with DEP stormwater management standards, design infiltration rates are based on the Rawls table for soils with sandy loam and loamy sand textures.

### **Conclusion**

The results provided in Tables One through Eight demonstrate that the project, with the stormwater controls in place, will result in an overall decrease both in peak runoff rates and total runoff volume discharged from the project site. The project will impact neither the municipal stormwater drainage system or abutting properties.

Additionally, a portion of the proposed roof and the majority of driveway surfaces will be collected and recharged. The stormwater management system as designed is consistent with MADEP Stormwater Management Policy and accepted design practice.

## MAP INFORMATION

The soil surveys that comprise your AOI were mapped at 1:25,000.

Please rely on the bar scale on each map sheet for map measurements.

Source of Map: Natural Resources Conservation Service

Web Soil Survey URL:

Coordinate System: Web Mercator (EPSG:3857)

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: Middlesex County, Massachusetts  
Survey Area Data: Version 17, Oct 6, 2017

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: Sep 12, 2014—Sep 28, 2014

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

## Description

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The soils in the United States are assigned to four groups (A, B, C, and D) and three dual classes (A/D, B/D, and C/D). The groups are defined as follows:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas. Only the soils that in their natural condition are in group D are assigned to dual classes.
